

Current Application And Planned Enterprise AI Stack

Short explanation for a reader who does not know the code: first the current end-to-end workflow, then the future Oracle-managed stack and flow.

Current End-To-End Workflow

How The Current Workflow Works

- ? A user request is first classified into one of three paths: general question, document flow, or comparison flow.
- ? Before an A2A agent is used, the application selects a matching A2A agent and checks that it is trusted.
- ? General questions go to internal retrieval first; if that is not strong enough, web search is used as a fallback.
- ? Document inputs are OCR-processed, stored into the knowledge layer, and can then be used for document-based question answering.
- ? Comparison requests OCR both documents and generate a structured comparison before the final response is returned.

Reader Tip

- ? This page is the current flow only.
- ? The next pages explain the current stack, where AGNTCY fits, and the planned Oracle-managed future state.

Current Stack And Where AGNTCY Fits

What each layer is doing today, and where AGNTCY participates in the runtime flow.

Current Stack

What We Use Today

- ? Business workflow router
- ? A2A agents
- ? A2A for agent-to-agent communication
- ? MCP tool servers for OCR, retrieval, and web search
- ? OCI-hosted LLM and embedding models
- ? Oracle database vector search

What Each Layer Is Used For

- ? Router: decides the request path
- ? A2A agents: handle focused AI tasks
- ? A2A: carries agent-to-agent requests
- ? MCP: executes OCR, retrieval, and web tools
- ? OCI models: generate answers, embeddings, and comparisons
- ? Oracle DB: stores and searches vectorized document content

Where AGNTCY Fits

Where AGNTCY Fits In The Flow

- ? AGNTCY is used in one important place in the runtime: before an A2A agent is invoked.
- ? It helps the application find a matching A2A agent by capability and verify that the selected A2A agent is trusted.
- ? After that, the application talks to the A2A agent over A2A as usual.

Oracle Enterprise AI Stack And What It Can Replace

The Oracle-managed capabilities mentioned in the reference and how they fit against the current application.

Oracle Enterprise AI Stack

Managed Runtime

- ? Projects
- ? IAM and authentication
- ? Responses API
- ? Conversations
- ? Streaming and structured outputs

Managed Memory

- ? Short-term memory
- ? Long-term memory
- ? Memory compaction

Managed Tools

- ? File Search
- ? Code Interpreter
- ? Function Calling
- ? Remote MCP
- ? SQL Search / NL2SQL
- ? Vector Stores, Files, Containers

What These Can Replace

Current Custom Piece -> Oracle Managed Replacement

- ? Custom final answer orchestration -> Responses API
- ? Custom multi-turn handling -> Conversations + short-term memory
- ? Custom vector-RAG over OCR content -> Files + Vector Stores + File Search
- ? Custom internal tool orchestration -> Function Calling
- ? Custom external tool integration -> Remote MCP
- ? No managed durable memory -> Long-term memory
- ? Custom execution-heavy workflows -> Code Interpreter + Containers
- ? Future database Q&A needs -> SQL Search / NL2SQL

Important Reading

? The goal is not to replace the business workflow. The goal is to keep the user experience and replace the lower-level AI runtime plumbing with Oracle-managed capabilities where it makes sense.

Current Flow Vs Planned Flow

The future state keeps the same business workflow but moves more of the AI runtime into Oracle-managed services.

What Changes And What Stays The Same

- ? Today: the application already has enterprise-style AI behavior, but much of the orchestration, retrieval, and tool integration is custom-built.
- ? Planned: keep the business workflow, keep AGNTCY only where it adds value in discovery and trust, and replace more of the low-level AI runtime with Oracle-managed agent capabilities.

One-Line Summary

- ? Current app = custom AI runtime on OCI. Planned app = same business flow with more Oracle-managed enterprise agent services underneath.
